CHAMELEONS MOVE ONE EYE AT A TIME

Chameleons are best known for being able to change skin color. But even more astounding is their super eyesight. Each of their two eyes sticks out from the head and is covered by a rounded eyelid with a small opening. And each eye can turn or rotate on its own! With this power, a chameleon can look forward and backward at the same time. It can hunt for insects to eat while looking out for danger. Once it has found prey or predator, it can focus both eyes to see it more clearly.

Chipmunks are super-powerful diggers! They dig tunnels, or burrows, in which they live. They are well equipped with extra-strong bones in all four legs, super-sharp front claws, and very hard nose pads. A chipmunk first makes a burrow opening with its head and nose. Then, with a swimming motion, it uses the claws on its front and rear feet to fling the dirt behind its body. Finally, it turns around and, like a bulldozer, pushes the dirt out of the burrow. Now it has a safe place to live and store its food!
